

The debate on the need to formulate new policies and improve current water management systems has once again been present in the world, and Chile is no stranger to this discussion.

Climatic phenomena such as droughts have increased in frequency and severity, which is mainly associated with climate change, and this trend is expected to continue or intensify. The relevance that this issue has taken should be addressed through the formulation of public policies that contemplate the management of water resources, with efficiency as the first focus.

That is why Salmones Camanchaca declares that the management of water resources is a priority within its business strategy, evaluating it within the organization's risk management.

Salmones Camanchaca is constantly implementing more efficient production actions within the entire value chain of its product, through control measures such as:

- Measuring the Water Footprint of our operation.
- Requiring our suppliers to contribute to the care and efficiency in water consumption, controlling or improving production processes.
- Visualizing possible conflicts around water resources, to avoid the risks associated with future emergencies.

For Salmones Camanchaca, water management, as an economic asset, is of great relevance, so we seek to achieve efficient and equitable use and favor the conservation and protection of water resources.
